## Description

# BLOW OUT PREVENTER

### BACKGROUND OF INVENTION

- [0001] The present invention relates to an oilfield tool seal and, in particular, to a blow out preventer for use during tubular string handling.
- [0002] During oilfield drilling and borehole completion operations tubular strings may be handled in the form of the drill string, the casing or liner string for lining the borehole, etc. In some operations, such as casing drilling and/or casing running, a casing clamp is used to grip the string at its upper end. In some cases, an inside gripping clamp may be used. An example of such a gripping clamp is described in WO00/19058 of Appleton, and assigned to the present assignee TESCO Corporation. Such clamps are available from the assignee and known as the Internal Drive Assembly CDS™.
- [0003] An inside gripping clamp includes a spear, gripping slips on the spear and a seal about the spear. The spear extends into the bore of a tubular being handled to position

the slips for engagement of the inner diameter of the tubular. During operation, mud is pumped down through the spear and the seal creates a seal against the inner diameter to maintain mud pressure in the tubular string. The seal generally is passive and operates against a pressure differential. An inside gripping clamp may be connected for manipulation by a top drive or other device, the entire assembly being suspended in a rig or derrick by a draw works.

- [0004] In a well control incident, it may be desirable to shut in the well, including sealing the upper end of the tubular string. If such an incident occurs during the use of an inside gripping clamp, well control may be achieved by reliance on the seal about the clamp's spear. As a next step, or where a failure of the passive is encountered, it may be desirable to support the tubular string in the floor of the derrick/rig and to remove the casing clamp from the tubular, such that the tubular string can be capped.
- [0005] In the situation where both the draw works and the spear seal fail, the well may be very difficult to control.

#### **SUMMARY OF INVENTION**

- [0006] In accordance with one aspect of the present invention, there is provided a blow out preventer for operating be-

tween a tubular gripping tool and a tubular gripped by the tool, the blow out preventer comprising: an expandable seal carried on the tubular gripping tool and expandable to seal between the tool and the tubular's inner wall, the expandable seal being operable as a back up to a primary seal operable between the tubular gripping tool and the tubular's inner wall.

- [0007] In accordance with another broad aspect of the present invention, there is provided an inside gripping clamp for gripping an oilfield tubular, the inside gripping clamp comprising: a spear sized to extend into the bore of a tubular to be gripped, gripping slips positioned on the spear and drivable to engage against the inner wall of the tubular to be gripped and a primary seal about the spear to create a seal between the spear the inner wall of the tubular, the primary seal being expandable in response to at least operationally generated fluid pressure differential in the tubular and a secondary seal about the spear selectively operable to create a seal between the spear the inner wall of the tubular.
- [0008] In accordance with another aspect of the present invention, there is provided a blow out preventer assembly for operating between a tubular gripping tool and a tubular

gripped by the tool, the blow out preventer comprising: an expandable seal carried on the tubular gripping tool and expandable to seal between the tool and the tubular's inner wall and a hydraulic drive means for selectively driving the expansion of the expandable seal.

[0009] In accordance with another broad aspect of the present invention, there is provided a method for shutting in a well while a tubular gripping tool remains positioned in the upper end of a tubular string extending into the well, the method comprising: providing an expandable seal about a spear of the tubular gripping tool that can be expanded selectively to seal between the spear and the inner diameter of a tubular and selectively expanding the seal to shut in the well.

#### **BRIEF DESCRIPTION OF DRAWINGS**

[0010] Figure 1 is a schematic illustration of a blow out preventer assembly.

[0011] Figure 2 is a schematic illustration of another blow out preventer assembly.

[0012] Figure 3 is an axial section along a tubular gripping tool including a primary seal and a backup expandable seal, with the left hand side showing the backup seal in a non-expanded condition and the right hand side showing the

backup seal in an expanded condition.

- [0013] Figure 4 is an axial section along a portion of a tubular gripping tool including a primary seal and a backup expandable seal, with the left hand side showing the backup seal in a non-expanded condition and the right hand side showing the backup seal in an expanded condition.
- [0014] Figure 5 is a quarter axial section along another tubular gripping tool with the left hand side showing the backup seal in a non-expanded condition and the right hand side showing the backup seal in an expanded condition.
- [0015] Figure 6 is a schematic illustration of another blow out preventer assembly.
- [0016] Figure 7 is a schematic illustration of another blow out preventer assembly.

#### **DETAILED DESCRIPTION**

- [0017] Referring to Figure 1, a blow out preventer assembly 10 is provided for operating between a tubular gripping tool, such as a casing clamp 12 of the internal gripping type, and a tubular 14 gripped by tool 12. Inside gripping clamp 12 may be connected for manipulation by a top drive 16 or other device, the entire assembly of top drive 16 and clamp 12 may be suspended in a rig or derrick 18 by a draw works 20.

- [0018] A mud flow path may be defined by lines and pipes 21a on the rig, a passage through the top drive 21b and an axial bore 21c through the clamp that opens at an end of a clamp spear 22 disposed in the tubular, when a tubular is gripped. The mud flow path provides that drilling fluid can be pumped from a mud supply to the tubular.
- [0019] In a well control incident such as a well kick or other pressure surge from the formation, it may be desirable to shut in the well, including sealing the upper end of the tubular string. If such an incident occurs during the use of an inside gripping clamp and the passive seal about the clamp and the draw works fails, the blow out preventer assembly 10 can be operated to create a seal between the clamp and the tubular inner wall, to in effect seal the upper end of the tubular string.
- [0020] The blow out preventer assembly may, as shown in Figure 6, include a secondary passive seal, such as a seal cup, positioned adjacent and upwardly of the primary seal. The secondary seal, therefore, may act as a back up should the primary seal fail.
- [0021] In another embodiment, as shown in Figure 1, the blow out preventer assembly may include an expandable seal 23 carried on the tubular gripping tool and expandable to

seal between the tool and the tubular's inner wall and a drive system 24a, 24b, 24c, 24d for the expandable seal. The drive system may be selected such that the seal is not normally driven out into engagement with the inner wall of the tubular, but only when it is necessary to contain a surge from the formation. In particular, it may be desirable that the drive means be selectively operable, for example, by other than a normal operational pressure differential such as by hydraulic or rotational drive. In a convenient embodiment for oilfield operations, the drive system may be hydraulically driven.

[0022] In the embodiment of Figure 1, for example, expandable seal 23 may be mounted between a retainer and a piston 24a and can be driven by applying hydraulic pressure against piston 24a such that it is driven against the seal to cause it to extrude outwardly. The drive actuator may be a ball drop mechanism 24b including a ball 24c that is sized to pass from the mechanism to a seat 24d to cause a seal in bore 21c through the clamp. Ball drop mechanism 24b is positioned upstream of the seat, in this illustration adjacent the top drive. Seat 24d is positioned downstream of the piston 24a in bore 21c such that a ball sealed against the seat can be used to increase the fluid pressure against

the piston to drive it against seal 23.

[0023] As will be appreciated, ball 24c may be a ball, a dart, a plug or other device that can pass through the mud flow path, but is sized to be stopped by and sealed against the seat. A ball drop mechanism can operate in many different ways, for example, by various mechanisms that may not be affected by normal drilling or tubular running operations, but may be actuated manually directly or remotely when a ball is to be released. Mechanisms may include, remotely or directly operated handles or valves, remotely or directly actuated solenoids, etc.

[0024] In another embodiment, such as that shown in Figure 2, the clamp may include an expandable seal 23, piston 24a and seat 24d. However, ball drop mechanism 26 is located further away from the top drive/clamp than in the embodiment of Figure 1. In this embodiment, the ball drop mechanism is positioned in a standpipe 28 adjacent the rig floor, which facilitates access thereto. The ball 24c is sized to pass through the ID of all of the mud flow lines 21a, through the top drive passage and through the axial bore of the clamp to reach seat 24d. It is to be understood that, in such arrangements, the ball drop mechanism can be installed anywhere upstream of the seat.

[0025] Another embodiment, as shown in Figure 7, may use an expandable seal 32 on the spear of a clamp and a seal selectively drivable to expand out into a sealing condition about the spear by a drive system 34 including hydraulic pressure independent from the drilling fluid flow, as through a flow conduit 35 through lines or internal passages.

[0026] Thus, each of the embodiments of Figures 1, 2, 6 and 7 provide a method for shutting in a well during use of a tubular gripping tool and when it remains positioned in the upper end of a tubular string extending into the well, which may occur during a well incident and when the passive seal of the clamp fails and the draw works cannot be operated to remove the clamp from the end of the tubing string. The method can include expanding an expandable seal, such as a secondary passive seal, seal 23 or seal 32, which is positioned about a spear 22 of the tubular gripping tool to create a seal between the spear and the inner diameter of the tubular string, thereby to seal the upper end of the tubular string.

[0027] The expandable seal may be expanded by a drive system that can be actuated selectively when it is desired to expand the seal. Various drive mechanisms may be useful,

such as an arrangement that uses drilling mud to drive expansion, as in Figures 1 and 2, a system using another form of hydraulic pressure or another drive system.

[0028] It may be useful to test the operation of the seal, since it may only be used occasionally, but when used may be of great importance. In a test, for example, it may be useful to conduct a flow test wherein a ball 24c is pumped from its release point to ensure that it can pass to seat without being obstructed.

[0029] With reference to Figure 3, an inside gripping clamp 112 is shown. Clamp 112 may be used for gripping an oilfield tubular 114 and may include an end 139 formed for connection to a top drive or other means for manipulating and/or suspending the clamp in a rig. Clamp 112 may include a spear 122 sized to extend into the bore of the tubular to be gripped, gripping slips 140 positioned on the spear and drivable to engage the tubular to be gripped, a bore 121 through the clamp and its spear through which drilling fluid can pass into the tubular and a primary seal 142 about the spear to create a seal between the spear the inner wall of the tubular. Primary seal 142 may be expandable in response to an at least operationally generated fluid pressure differential in the tubu-

lar. Clamp 112 may further include a secondary seal 123 about the spear which is selectively operable to create a seal between the spear the inner wall of the tubular and, therefore, may be operated as a blow out preventer as a back up to primary seal 142. An enlarged view of the portion of the clamp about the primary and secondary seals is shown in Figure 4.

- [0030] As will be appreciated, clamp 112 may include any or all of the various additional parts shown in the illustrated embodiment such as a stabbing guide, a mud saver valve, a tubular stop flange, etc. Slips 140 and the drive system for the slips may take various forms, including those forms illustrated.
- [0031] In normal operation of clamp 112, spear 122 is inserted into a tubular bore to grip the tubular during connection to or break out from a tubular string. When spear 122 is inserted into a tubular, primary seal 142 may seal against the inner wall of the tubular to contain drilling fluids in the tubular. In this normal operation, secondary seal 123 is maintained in a non-expanded condition such that it remains spaced from or not actively sealed against the tubular inner wall. This is shown on the left hand quarter sections of Figures 3 and 4.

[0032] Should a back up for primary seal 142 be necessary, seal 123 can be expanded to seal against the tubular inner wall.

[0033] Although many drive systems are possible, the drive system illustrated in Figures 3 and 4, acts by release of a ball 124c from a ball drop mechanism somewhere upstream of a seat 124d in bore 121. Ball 124c may be pumped with the drilling mud flow into the clamp to seal against seat 124b so that mud pressure can be used to inflate the seal.

[0034] Seal 123, as in the illustrated embodiment, may be an extrudable ring packer mounted between a fixed retainer ring 150 and a piston ring 124a, shown as a two-part arrangement including a piston face 152. Piston face 152 may be open in a hydraulic chamber 154 in fluid communication with bore 121. Piston ring 124a may be secured in position by one or more shear pins 156. Shear pins 156 may be selected to prevent movement of piston 124a under normal pressures but to permit movement when fluid pressures in excess of a selected rating are applied against face 152. An example of normal operational pressure where the packer would not be activated is 3,000 psi. In this case the shear pins may be set to actuate at 3,500 to 3,750 psi. A ratchet arrangement 158 may be disposed

between spear 122 and piston ring 124a to lock the piston into its pressure driven, energized position.

- [0035] As noted, pressures sufficient to shear pins 156 may be applied by landing a ball 124c against seat 124d such that pressure can be increased above the ball. This increased pressure may be communicated, arrows P, to chamber 154 and against face 152. Induced movement of piston 124a causes seal 123 to extrude out, arrow E, between the piston and retainer 150.
- [0036] In another embodiment, shown in Figure 5, a hydraulic drive system that operates on a hydraulic source other than mud pressure in bore 121 can be used to drive expansion of the seal. In particular, piston 124a is operated by hydraulic fluid from a source pumped through passages 160 passing through the body of spear 122 into hydraulic chamber 154. Seals, such as o-rings 162 may be required at connections between the parts of the clamp.
- [0037] The clamp and its various parts may be made of materials and with methods conducive to use in the oilfield industry, as will be appreciated.
- [0038] The foregoing description is illustrative of various embodiments and changes may be made thereto without departing from the spirit of the invention.

## Claims

- [c1] 1. A blow out preventer for operating between a tubular gripping tool and a tubular gripped by the tool, the blow out preventer comprising: an expandable seal carried on the tubular gripping tool and expandable to seal between the tool and the tubular's inner wall, the expandable seal being operable as a back up to a primary seal operable between the tubular gripping tool and the tubular's inner wall.
- [c2] 2. An inside gripping clamp for gripping an oilfield tubular, the inside gripping clamp comprising: a spear sized to extend into the bore of a tubular to be gripped, gripping slips positioned on the spear and drivable to engage against the inner wall of the tubular to be gripped and a primary seal about the spear to create a seal between the spear and the inner wall of the tubular, the primary seal being expandable in response to at least an operationally generated fluid pressure differential in the tubular and a secondary seal about the spear selectively operable to create a seal between the spear and the inner wall of the tubular.
- [c3] 3. A blow out preventer assembly for operating between a

tubular gripping tool and a tubular gripped by the tool, the blow out preventer comprising: an expandable seal carried on the tubular gripping tool and expandable to seal between the tool and the tubular's inner wall and a hydraulic drive means for selectively driving the expansion of the expandable seal.

[c4] 4. A method for shutting in a well while a tubular gripping tool remains positioned in the upper end of a tubular string extending into the well, the method comprising: providing an expandable seal about a spear of the tubular gripping tool that can be expanded selectively to seal between the spear and the inner diameter of a tubular and selectively expanding the seal to shut in the well.
